<<NOTE TO USER: Please add details of the date, time, place and sponsorship of the meeting for which you are using this presentation in the space indicated.>>

This presentation on Children and Noise is part of a comprehensive set of training materials for health care providers on children, the environment and health.

<<NOTE TO USER: This is a large set of slides from which the presenter should select the most relevant ones to use in a specific presentation. These slides cover many facets of the problem. Present only those slides that apply most directly to the local situation in the region. It is also very useful if you present regional/local examples of noise prevention programs, if available, and choose local relevant pictures.>>

CONTENTS

- 1. Introduction**
- 2. Vulnerability of children**
- 3. Adverse health effects**
- 4. Effects by age-group**
- 5. Taking action**
- 6. Discussion**

LEARNING OBJECTIVES

To **understand, recognize** and **know**

1. Definition and characteristics of sound and noise
2. Sources and settings of noise exposure
3. Adverse effects of noise exposure
 - On physical health
 - On psychological health
 - On cognition
4. **Weight of the evidence of the harm to children**
 - **Special vulnerability of children**
 - **Various noise exposure scenarios in settings where children develop**
5. Interventions and preventive strategies

These are the learning objectives for this module. After the presentation, the audience should understand, recognize and know

<<READ SLIDE>>

6. Discussion

Children and noise

DEFINITION: SOUND AND NOISE

Sound is characterized by:

❖ Vibration

- Frequency (Hz)
- Intensity (Pa or dB)
 - Decibel scale logarithmic
 - Begins at threshold of hearing

❖ Periodicity

❖ Duration

“Noise is an unwanted or objectionable sound”

5

What is sound? Sound is a mechanic vibration propagated by elastic media (as air and water) which alters the pressure displacing the particles, and can be recognized by a person or an instrument.

Vibration and noise can never be separated but vibration can exist without audible noise.

Sound is characterized by its intrinsic characteristics:

• **Vibration:** Sound is a mechanic vibration, expressed as a combination of pressure (Pascals, Pa) and frequency (Hertz, Hz)

• **Frequency** or pitch is the number of cycles per second (Hertz, Hz or kilo Hertz, KHz).

• **Intensity** or loudness is the “level of sonorous pressure” and is measured in Pascals (Pa) or decibels (dB). The audible spectrum of the human ear is between 0.00002 Pa (corresponds to 0 dB) and 20 Pa (corresponds to 120 dB). The intensity of human speech is approximately 50 dB. Decibels are used for convenience to express sound on a compressed, logarithmic scale in the human audible spectrum.

• **Periodicity:** describes the pattern of repetition of a sound within a period of time: short sounds that are repeated.

• **Duration:** is the acoustic sense developed by the continuity of a sound in a period of time, for example music, voice or machinery.

What is noise? Noise is an unwanted or objectionable sound. Generally, the acoustic signals that produce a pleasant sense (music, bells) are recognized as “sound” and the unpleasant sounds as “noise” (for example: produced by a machine or airplane). It can be a pollutant and environmental stressor, and the meaning of sound is important in determining reaction of different individuals to the same sound. One person’s music is another’s noise.

The human ear is an instrument that detects vibration within a set range of frequencies. Air, liquid or solid propagates vibration; without them, sound does not exist. Sound does not exist in the vacuum. The higher the level of pressure of the sonorous wave, the shorter the period of time needed to be perceived by the ear.

Why are not all vibrations audible?

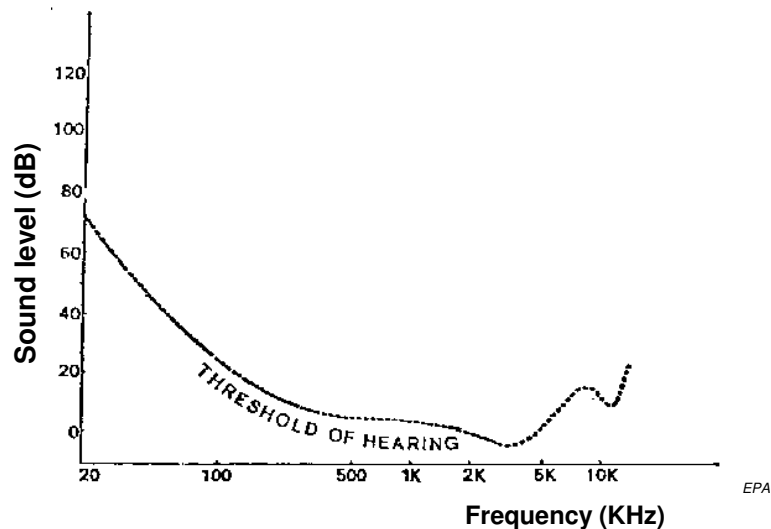

The ear is a frequency analyzer. The eardrum separates tone and conduction in two different ways: by the nervous system and by the bones. The nervous system connects the cochlea to the temporal region of both hemispheres of the brain. The cochlea perceives vibration transmitted directly from the bones of the head.

Children and noise

THRESHOLDS OF HUMAN HEARING

6

Why is noise sometimes inaudible?

Threshold of hearing is defined as the minimum efficient sonorous pressure (Pa or dB) that can be heard without background noise of a pure tone at a specific frequency (Hz or KHz, cycles per second).

The human audible frequency range is from 20 to 20,000 Hertz (Hz). Frequencies out of this range are not detected by the human ear. The ear is not equally sensitive to all the frequencies.* The most audible frequencies are between 2000 and 3000 Hz (range within which the least pressure is needed to provoke the conscious recognition of a sound). This range can be easily identified where the curve is at its minimum and corresponds to human speaking frequencies.

For this reason, sound meters are usually fitted with a filter whose response to frequency is a bit like that of the human ear. The most widely used sound level filter is the A scale, which roughly corresponds to the inverse of the 40 dB (at 1 kHz) equal-loudness curve. Using this filter, the sound level meter is thus less sensitive to very high and very low frequencies. Measurements made on this scale are expressed as **dB(A)**.

The "normal threshold" of hearing is defined in "young people with a healthy auditory system".

The **"pain threshold"** is the high level (high dB) audible sound where the level of pressure of the sound produces discomfort or pain. The pressures of the sounds are over the curve: "ultrasounds". Very powerful levels of sound can be perceived by the human ear but cause discomfort and pain.

*Pressures below the audible level are called "infra-sounds": the pressure is detected but our hearing mechanism is not adapted to making the sound evident to the human ear (under the curve in the graphic). These frequencies (less than 20 Hz, not audible for the human ear) can be produced by machines or "ultrasonic" motors of planes. Out of the limits of the human threshold of hearing exists sound that can be perceived by special equipment or animals such as dolphins and bats that are equipped to perceive sound that humans can not perceive. The human being hears a very short portion of the existing sounds, the very weak and the ones above and below of the thresholds are not perceived or they are accompanied by pain, **and can produce damage to a system that is not prepared to perceive them as the person may not be able to protect her/himself from this deleterious exposure.** There is individual variation within these general parameters.

Children and noise

MAGNITUDE AND EFFECTS OF SOUND

COMMON EXAMPLE	dBA	EFFECT
Breathing	0-10	Hearing threshold
Conversation at home	50	Quiet
Freeway traffic (15 m), vacuum cleaner, noisy party	70	Annoying , intrusive, interferes with phone use
Average factory, train (at 15 m)	80	Possible hearing damage
Jet take-off (at 305 m), motorcycle	100	Damage if over 1 minute
Thunderclap, textile loom, chain saw, siren, rock concert	120	Human pain threshold
Toy cap pistol, Jet takeoff (at 25 m), firecracker	150	Eardrum rupture

7

This abbreviated table correlates common sounds with effects on hearing.

Additional examples for discussion are listed below:

-Quiet suburb or quiet conversation	50 dB A	No significant effect
-Conversation in a busy place, background music or traffic	60 dB A	Intrusive
-Freeway traffic at 15 metres	70 dB A	Annoying
-Average factory, train at 15 metres	80 dB A	Possible hearing damage
-Busy urban street, diesel truck	90 dB A	Chronic hearing damage if exposure over 8 hours
-Subway noise	90 dB A	Chronic hearing damage, speech interfering
-Jet take-off 300 metres	100 dB A	More severe than above
-Stereo held close ear	110 dB A	More severe than above
-Live rock music, jet take off 160 mts	120 dB A	As above, human pain threshold
-Earphones at loud level	130 dB A	More severe than above
-Toy cap pistol, firecracker close ear	150 dB A	Acute damage (eardrum rupture)

dBA weighting curve: response of a filter that is applied to sound level meters to mimic (roughly) the response of human hearing. So a typical human equal loudness curve is somewhat similar to the dBA curve, but inverted.

Children and noise

SOURCES OF NOISE

Outdoor sources

- ❖ Transport
 - Aircraft
 - Road
 - Rail
- ❖ Occupational
 - Machinery
- ❖ Neighbours
 - Machinery
 - Loud music

Indoor sources

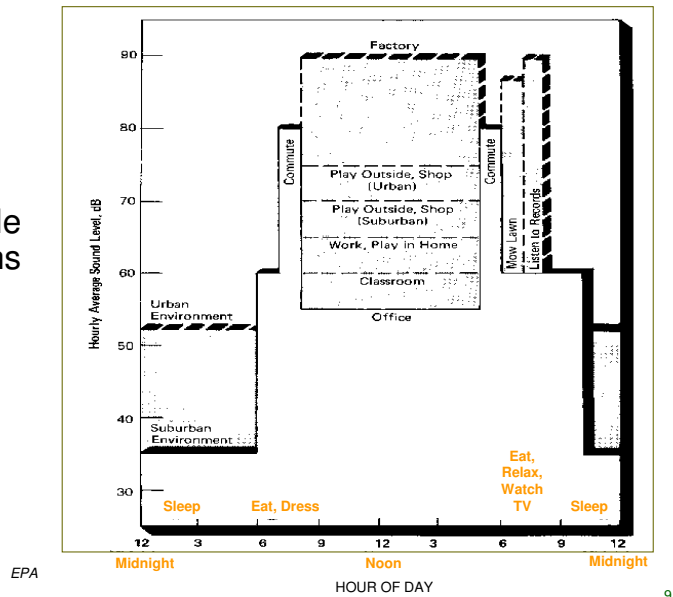

- ❖ Ambient noise outside
- ❖ Building design and location
- ❖ Room acoustics
- ❖ Activities of occupants
 - Children

Common sources of outdoor noise arise from transportation (aircraft, car and truck traffic, and trains), occupations (construction machinery, assembly lines), and even from neighbours (yard equipment, loud music). Indoor noise is affected by outdoor noise, and indoor sources such as TV, radio, music and children at play. The level is modified by building design and location as well as room acoustics.

Children and noise

SETTINGS OF NOISE EXPOSURE: “NOISE-SCAPE”

Hypothesized lifestyle noise exposure patterns

The concept of a “noise-scape” can be useful in thinking about noise exposures. That is, obvious loud noises are imposed upon a background of noises that will vary according to general location (urban vs. rural), time of day (day vs. night) and activity (school vs. play). This image is a schematic representation which illustrates these different aspects of the “noise-scape”.

Reference:

•Noise effects handbook, National Association of Noise Control Officials. *Office of the Scientific Assistant, Office of Noise Abatement and Control, U.S. Environmental Protection Agency*, 1979, revised 1981 (www.nonoise.org/library/handbook/handbook.htm).

Picture:

Children and noise

NOISE EXPOSURE IN EU

- ❖ 40% of population exposed to $L_{eq} > 55$ dBA during the day
- ❖ 20% of population exposed to $L_{eq} > 65$ dBA during the day
- ❖ 30% of population exposed to $L_{max} > 55$ dBA during the night
- ❖ Hazard is increasing

10

L_{eq} : average sound level over the period of the measurement, usually measured A-weighted

L_{max} : maximum A-weighted noise level

dBA weighting curve: response of a filter that is applied to sound level meters to mimic (roughly) the response of human hearing. So a typical human equal loudness curve is somewhat similar to the dBA curve, but inverted.

- Berglund B et al., eds. Guidelines for Community Noise. Geneva, *WHO*, 1999.

Children and noise

NOISE CONTAMINATION

❖ Noise exceeding safety threshold is widespread:

- In neighbourhoods
- Schools, hospitals and care centres
- Urban and suburban areas
- Activities inside the buildings (elevators, water tubs, music in discotheque)
- From children themselves (toys, equipment, children playing or practicing sports in a close yard)
- Traffic: heavy road, railways, highways, subways, airports
- Industrial activities
- Building and road construction, renovation

❖ Increased environmental noise levels - more noise sources

❖ Also linked to population growth

11

Noise contamination or noise pollution is a concept which implies harmful levels of excess noise. Noise intense enough to cause harm is widely spread.

Children and noise

VULNERABLE GROUPS OF CHILDREN

- ❖ The fetus and babies
- ❖ Preterm, low birth weight and small for gestational age babies
- ❖ Children with dyslexia and hyperactivity
- ❖ Children on ototoxic medication

13

It is logical to consider certain subgroups of children (since conception) to be particularly at risk for harm from excess noise exposure. These include the fetus, babies and very young infants born preterm, with low birth weight or small for gestational age. Also, children who have learning disabilities or attention difficulties may be more likely to develop early problems with mild hearing loss compared to children without these challenges, and children on ototoxic medications may have higher likelihood of developing problems from exposure to excess noise.

Reference:

•Carvalho WB, et al. Noise level in a pediatric intensive care unit. *J Pediatr*, 2005, 81:495-8.

OBJECTIVES: The purpose of this study was to verify the noise level at a PICU. METHODS: This prospective observational study was performed in a 10 bed PICU at a teaching hospital located in a densely populated district within the city of São Paulo, Brazil. Sound pressure levels (dBA) were measured 24 hours during a 6-day period. Noise recording equipment was placed in the PICU access corridor, nursing station, two open wards with three and five beds, and in isolation rooms. The resulting curves were analyzed. RESULTS: A basal noise level variation between 60 and 70 dBA was identified, with a maximum level of 120 dBA. The most significant noise levels were recorded during the day and were produced by the staff. CONCLUSION: The basal noise level identified exceeds International Noise Council recommendations. Education regarding the effects of noise on human hearing and its relation to stress is the essential basis for the development of a noise reduction program.

VULNERABILITY OF CHILDREN

- ❖ Different perception of dangers of noise
 - Can not recognize the dangerous exposures
- ❖ Lack of ability to control the environment
 - Are not able to identify and avoid the source of noxious noise
 - Exposure *intra utero*
- ❖ Noise can interfere with communication of danger
- ❖ May be more exposed due to their behaviour
 - Exploratory or risk behaviour (in children and teenagers)

Special vulnerability of children to noise. The known increased risk is due to

Children and noise

VULNERABILITY OF CHILDREN

Why might children be more susceptible to noise effects?

- ❖ Possible increased risk due to immaturity
Increased cochlear susceptibility?
 - *In utero*
 - Animal data studies
- ❖ Critical periods in relation to learning
- ❖ Lack of developed coping repertoires
- ❖ Vulnerable tasks \ Vulnerable settings (schools, home, streets)

What might be the implications of noise effects?

- ❖ Lifelong impairment of learning and education
- ❖ Short-term deficit followed by adaptation
- ❖ Non intentional lesions

15

<<READ SLIDE>>

Exposure to excessive noise and vibration during pregnancy may result in high frequency hearing loss in the newborn, may be associated with prematurity and growth retardation, although the scientific evidence remains inconclusive.

The role of the amniotic fluid is not yet defined, nor when and which noises or vibrations can damage the fetal development of the auditory system (e.g. cochlea). Concern about synergism between exposure to noise and ototoxic drugs remains incompletely defined. There are studies on fetal audition dating from 1932 that explore the reaction of the fetus to external noises but even today this remains incompletely characterized.

ADVERSE EFFECTS FROM EXCESS NOISE EXPOSURE

- ❖ Direct ear damage
 - Noise induced hearing loss
 - Noise induced threshold shift
- ❖ Indirect adverse effects
 - Physiological effects
 - Psychological effects
- ❖ Impaired cognition

Characteristics of the sound can modify effect

Adverse effects can be divided into direct damage, indirect adverse effects and impaired cognition. Many effects of noise exposure are more thoroughly studied in adults than in children.

The degree of adverse effect is modified by the sound characteristics.

•**Vibration:** can be acute or chronic, audible or inaudible. Vibration can be transmitted to all the body directly through the skin or bones.

•**Frequencies:** lower and higher (ultra and infra sounds) can also damage the human hearing system, despite being imperceptible, and have important consequences for life (loss of hearing). These consequences can also be present after chronic exposure to low frequency non audible sounds (chronic back noise exposure). Incubators are an example of this exposure.

•**Intensity:** Direct blows to the ears, very loud noise (pneumatic hammer or drill, fire arms, rocket), and sudden but intense sounds can destroy the eardrum and damage the hair cells of the cochlea by bypassing the protective reflexes. Acute trauma can cause a lifelong lesion.

•**Periodicity and Duration:** Impulse noise is more harmful than continuous because it bypass the natural protective reaction, the damping-out of the ossicles mediated by the facial nerve. Loud noise may result in temporary decrease in the sensitivity of hearing and tinnitus, but repeated exposure may cause these temporary conditions to become permanent.

ORGAN DAMAGE NOISE INDUCED HEARING LOSS

Normal hair cell

VIMM

Noise damaged hair cell

VIMM

18

Normal healthy "hair cells" transform vibration into nerve impulses sending messages to the brain. Trauma to the hair cells of the cochlea results in hearing loss. Prolonged exposure to sounds louder than 85 dBA is potentially injurious (85 dBA is tolerable for an occupational exposure). Continuous exposure to hazardous levels of noise tend to affect high frequencies regions of the cochlea first. Noise induces hearing loss gradually, imperceptibly, and often painlessly. Often, the problem is not recognized early enough to provide protection. Further, it may not be recognized as a problem, but merely considered a normal consequence of ordinary exposure, and part of the environment and daily life.

AUDIOGRAM

Noise-induced hearing loss

OSHA

<< NOTE TO USER: If possible place an audiogram of a child living in your local environment here to illustrate either normal hearing, or hearing damaged by environmental noise. >>

Noise-induced hearing loss is insidious, but increases with time, usually beginning in adolescent years. As shown here, it affects the high frequencies first. The speech window is between 500 and 4000 Hz, so it is not surprising that high frequency loss of large magnitude could go undetected for long periods of time without formal testing.

Picture:

- OSHA (U.S. Department of Labor Occupational Safety & Health Administration) www.osha.gov/dts/osta/otm/noise/images/sensorineural_loss_audiogram.gif

CHILDREN AND NOISE: SETTINGS

Noise at home	50 - 80 dB A
Home appliances	78 - 102 dB A
Noise in incubators	60 - 75 dB A, peak sounds 120 dB A
Noise in hospitals	> 70 dB A
Day-care institutions	75 – 81 dB A
Noise from toys peak sounds	79 - 140 dB A
Background noise in schools	46.5 – 77.3 dB A

These ranges represent excessive everyday exposures of children to sound.

NOISE INDUCED THRESHOLD SHIFT (NITS)

- ❖ Initially - a temporary condition
 - Decrease in sensitivity to noise
 - Tinnitus

- ❖ Caused by exposure to loud noises

- ❖ May be reversible or irreversible
 - Severity and duration of exposure
 - Continuous and recurrent exposure

Exposure to loud noise may result in a temporary decrease in the sensitivity of hearing and tinnitus. This condition, called temporary noise-induced threshold shift (NITS), lasts for several hours depending on the degree of exposure, and may become permanent depending on the severity and duration of noise exposure. Noise induced threshold shifts may be reversible; however, continued excessive noise exposure could lead to progression of NITS to include other frequencies and lead to increase severity and permanent hearing loss. The consequences of these measured NITS may be enormous if they progress to a persistent minimal sensorineural hearing loss. In school-aged children, minimal sensorineural hearing loss has been associated with poor school performance and social and emotional dysfunction.

PREVALENCE NOISE INDUCED THRESHOLD SHIFTS

National survey US children (n=5249)

Characteristics	%	(95% CI)
Age: 6-11 years old	8.5	(6.9-10.0)
12-19 years old	15.5	(13.3-17.6)
Sex:		
Male	14.8	(12.3-17.3)
Female	10.1	(8.3-11.8)
Urban status:		
Metropolitan	11.9	(9.8-14.0)
Non-metropolitan	13.0	(11.3-14.6)

Niskar AS, Pediatrics, 2001, 108(1):40-3

22

This is evidence that children are experiencing changes in hearing which are consistent with excess noise exposure. These data show the prevalence of Noise Induced Threshold Shift (NITS) in children which increases with age. The prevalence of NITS in one or both ears among children 6-19 year of age in the USA was recently found to be 12.5% (or 5.2 million) children affected. Most children with NITS have an early phase of NITS in only one ear and involving only a single frequency, however among children with NITS, 4.9% had moderate to profound NITS. This table demonstrates several points. First, older children have a higher prevalence of NITS compared to younger children suggesting that ongoing exposure to excess noise in the environment may be causing cumulative hearing damage. Boys in this survey were more likely to have evidence of excess noise exposure measured as NITS compared to girls, but there was little difference between urban and non-urban status.

Reference:

•Niskar AS. Estimated prevalence of noise-induced hearing threshold shifts among children 6 to 19 years of age: the Third National Health and Nutrition Examination Survey, 1988-1994, United States. *Pediatrics*, 2001, 108(1):40-3

This analysis estimates the first nationally representative prevalence of noise-induced hearing threshold shifts (NITS) among US children. Historically, NITS has not been considered a common cause of childhood hearing problems. Among children, NITS can be a progressive problem with continued exposure to excessive noise, which can lead to high-frequency sound discrimination difficulties (eg, speech consonants and whistles). The Third National Health and Nutrition Examination Survey (NHANES III) was conducted from 1988 to 1994. NHANES III is a national population-based cross-sectional survey with a household interview, audiometric testing at 0.5 to 8 kHz, and compliance testing. A total of 5249 children aged 6 to 19 years completed audiometry and compliance testing for both ears in NHANES III. The criteria used to assess NITS included audiometry indicating a noise notch in at least 1 ear. RESULTS: Of US children 6 to 19 years old, 12.5% (approximately 5.2 million) are estimated to have NITS in 1 or both ears. In the majority of the children meeting NITS criteria, only 1 ear and only 1 frequency are affected. In this analysis, all children identified with NITS passed compliance testing, which essentially rules out middle ear disorders such as conductive hearing loss. The prevalence estimate of NITS differed by sociodemographics, including age and sex. CONCLUSIONS: These findings suggest that children are being exposed to excessive amounts of hazardous levels of noise, and children's hearing is vulnerable to these exposures. These data support the need for research on appropriate hearing conservation methods and for NITS screening programs among school-aged children. Public health interventions such as education, training, audiometric testing, exposure assessment, hearing protection, and noise control when feasible are all components of occupational hearing conservation that could be adapted to children's needs with children-specific research.

INDIRECT ADVERSE EFFECTS

- ❖ **Stress-related somatic effects**
 - Stress hormone
 - Blood pressure
 - Muscle spasm

- ❖ **Psychological effects**
 - Annoyance / Isolation
 - Sleep disturbance
 - Mental health

- ❖ **Cognitive effects**
 - Reading, concentration, memory, attention

The next section will review the indirect adverse effects of noise listed here.

PHYSIOLOGICAL EFFECTS OF NOISE

There might be harmful consequences to health during the state of alertness as well as when the body is unaware or asleep.

24

There are a variety of physiological effects that have been documented or postulated as a result of excess noise exposure.

+ increase with noise, - decrease with noise, 0 no effect

Adapted from Babisch W, Noise Health, 2003, 5(18):1-11

In experimental studies with humans carried out in the laboratory, unequivocal findings of noise exposure on the endocrine system have been sometimes observed. However, exposure conditions vary considerably between experiments. Furthermore, secretory patterns of hormone excretion vary between individuals. It is not clear as to what extent findings from experimental studies on endocrine responses of noise reflect a potential health hazard. To more completely characterize these indirect adverse effects of excess noise, there is a need to 1) develop a consensus on measurement techniques, 2) replicate results of adult studies in children, and 3) link hormone levels to health impairment. When it is done, stress hormone responses may identify risk groups.

Leq: average sound level over the period of the measurement, usually measured A-weighted

N°: number of subjects

Reference:

•Babisch W. Stress hormones in the research on cardiovascular effects of noise. *Noise Health*, 2003, 5(18):1-11

In recent years, the measurement of stress hormones including adrenaline, noradrenaline and cortisol has been widely used to study the possible increase in cardiovascular risk of noise exposed subjects. Since endocrine changes manifesting in physiological disorders come first in the chain of cause-effect for perceived noise stress, noise effects in stress hormones may therefore be detected in populations after relatively short periods of noise exposure. This makes stress hormones a useful stress indicator, but regarding a risk assessment, the interpretation of endocrine noise effects is often a qualitative one rather than a quantitative one. Stress hormones can be used in noise studies to study mechanisms of physiological reactions to noise and to identify vulnerable groups. A review is given about findings in stress hormones from laboratory, occupational and environmental studies.

BLOOD PRESSURE - AIRCRAFT NOISE

Study	Psys (mmHg)	Pdia (mmHg)	Sound level (Leq)
Karagodina, 1969	abnormalities	abnormalities	distance from airport
Cohen, 1980	3-7	3-4	<70 dBA (indoors)
Cohen, 1981	no effect	no effect	70 dBA (indoors)
Evans, 1995	2	0	68 dBA (outdoors)
Evans, 1998	3	3	64 dBA (outdoors)
Morrell, 1998	negative	negative	ANE I 45 (outdoors)
Morrell, 2000	no effect	negative	ANE I 45 (outdoors)

- ❖ Inconsistent picture: 3 positive, 4 negative studies
- ❖ Prospective studies: 1 positive, 1 negative study
- ❖ Magnitude of effect found in positive studies may be relevant

Studies on elevated blood pressure and noise exposure (from aircraft) are also inconsistent. Only the cross-sectional study of Cohen shows that aircraft noise exposure (specifically at school) is statistically significantly associated with increases in systolic and diastolic blood pressure.

Leq: average sound level over the period of the measurement, usually measured A-weighted

Psys: systolic pressure

Pdia: diastolic pressure

dBA weighting curve: response of a filter that is applied to sound level meters to mimic (roughly) the response of human hearing.

So a typical human equal loudness curve is somewhat similar to the dBA curve, but inverted.

ANEI: Australian Noise Exposure Index.

BACKGROUND: Conclusions that can be drawn from earlier studies on noise and children's blood pressure are limited due to inconsistent results, methodological problems, and the focus on school noise exposure. OBJECTIVES: To investigate the effects of aircraft and road traffic noise exposure on children's blood pressure and heart rate. METHODS: Participants were 1283 children (age 9-11 years) attending 62 primary schools around two European airports. Data were pooled and analysed using multilevel modelling. Adjustments were made for a range of socioeconomic and lifestyle factors. RESULTS: After pooling the data, aircraft noise exposure at school was related to a statistically non-significant increase in blood pressure and heart rate. Aircraft noise exposure at home was related to a statistically significant increase in blood pressure. Aircraft noise exposure during the night at home was positively and significantly associated with blood pressure. The findings differed between the Dutch and British samples. Negative associations were found between road traffic noise exposure and blood pressure, which cannot be explained. CONCLUSION: On the basis of this study and previous scientific literature, no unequivocal conclusions can be drawn about the relationship between community noise and children's blood pressure.

HYPERTENSION AND EXPOSURE TO NOISE NEAR AIRPORTS *The HyENA study*

Results

- ❖ Significant exposure-response relationship
- ❖ Night time aircraft noise exposure: borderline significant relationship
- ❖ Risk of myocardial infarction in relation to noise exposure: analysis ongoing
- ❖ Effects of noise exposure on stress hormone level (cortisol): statistical analyses and epidemiological ongoing

Conclusion

- ❖ Prevalence of hypertension increased with increasing noise exposure
- ❖ Long-term road traffic noise exposure effects on BP
- ❖ Acute effect on hypertension of night-time aircraft noise
- ❖ Highly annoyed people are found at aircraft noise levels

27

An increasing number of people live near airports with considerable noise and air pollution. The Hypertension and Exposure to Noise near Airports (HYENA) project aims to assess the impact of airport-related noise exposure on blood pressure (BP) and cardiovascular disease using a cross-sectional study design.

Although the study has been made in adults (men and women between 45-70 years old), it might be a good cardiovascular disease predictor in children.

PSYCHOLOGICAL DAMAGE

- ❖ Exposure to **moderate level of noise** can cause
 - Psychological stress
 - Annoyance, interference with activity, isolation
 - Headache, tiredness and irritability; may impair intellectual function and performance of complex tasks
- ❖ Exposure to **intense level of noise** can
 - Cause personality changes and aggressive/violent reactions
 - Reduce ability to cope
 - Alter work performance and intellectual function
 - May cause muscle spasm and also break a bone (when combined with strong vibration)
 - Sleep disturbance
 - Changes in mental health.
- ❖ Exposure to **sudden, unexpected noise** can cause
 - Startle reaction with stress responses
 - Cause non intentional injuries

Psychological effects correlate with intensity (or loudness) of the noise.

Exposure to **moderate levels of noise** can cause psychological stress.

Other effects can be:

- Annoyance (fear, anger, feeling bothered, feelings of being involuntarily and unavoidably harmed, and feelings of having privacy invaded), interference with activity.
- Headache, tiredness and irritability are also common reactions to noise.
- Possible impairment of intellectual function and performance of complex tasks. Depends on the nature of sound and individual tolerance.

Exposure to **intense level of noise** can:

- Cause personality changes and provoke aggressive and violent reactions.
- Reduce ability to cope.
- Alter work performance and intellectual function.
- Cause muscle spasm and also break a bone (when combined with strong vibration).
- Cause sleep disturbance.
- Provoke changes in mental health.

Exposure to **sudden, unexpected noise** can cause:

- Startle reaction with stress responses.
- Cause non intentional injuries.

Stress response consisting in acute terror and panic was described in children upon exposure to sonic booms.

IMPAIRED COGNITIVE FUNCTION

- ❖ Chronic noise exposure impairs cognitive function
 - Reading comprehension
 - Long term memory
- ❖ Dose-response relationships
 - Supported by both laboratory and field studies
- ❖ Study of possible mechanisms and noise reduction interventions
 - Tuning out of attention / concentration
 - Impairment of auditory discrimination

The most robust area of study on noise and effects in children comes from studies which evaluate the effect of noise on learning and cognitive function; there are possible mechanisms, including noise-related changes in attention or distraction and impaired auditory discrimination.

<<READ SLIDE>>

ENVIRONMENTAL NOISE AND COGNITIVE DEVELOPMENT IN PRESCHOOL CHILDREN

- ❖ Children 6 months - 5 years
- ❖ Inverse associations between noise level at home and cognitive development

Wachs TD. *Early Experience and Human Development*. New York Plenum, 1982
Evans GW. *Children's Environments*, 1993, 10(1):31-51

Effects of noise on cognitive development have been documented in preschool ages as well. Higher levels of noise at home are associated with decrements in cognitive development for age.

APARTMENT NOISE AND READING ABILITY

- ❖ 54 children living in apartments above interstate highway
 - 32nd floor: 55 dBA,
 - 20th floor: 60 dBA,
 - 8th floor: 66 dBA
- ❖ Measures of auditory discrimination and reading ability
- ❖ Correlations between floor level and auditory discrimination vary by duration of residence
- ❖ **Floor level correlates with reading-abolished by adjustment for auditory discrimination**
- ❖ Reading powerfully associated with mothers' education

Cohen S. *Journal of Experimental and Social Psychology*, 1973, 9:407-22.

31

This study shows that street traffic noise measured on different floors of a multilevel apartment correlates inversely with auditory discrimination and reading ability. The higher floors were quieter and children scored better on reading ability and auditory discrimination. Correlations varied with duration of residence, and when reading level scores were adjusted for auditory discrimination measures, the floor level effect disappeared. Reading is also powerfully associated with mother's education.

Reference:

•Cohen S. Apartment noise, auditory discrimination, and reading ability in children. *Journal of Experimental and Social Psychology*, 1973, 9:407-22.

RAILWAY NOISE AND READING SCORES

- ❖ Reading scores compared between classes in same school
- ❖ Exposed/not exposed to railway noise
- ❖ No selection of children into classes
- ❖ **Poorer performance on achievement test on noisy side**
- ❖ Measuring reading age 3-4 months behind on noisy side

Bronzaft AL. *Environment and Behavior*, 1975, 7:517-28

32

This study compared reading scores between classrooms in the same school that were exposed and not exposed to railway noise. Poorer performance was noted on the noisy side with a 3-4 month delay compared to the quieter side. There was no selection of the children in each class. This is supportive evidence that noise impaired reading learning.

IMPAIRED COGNITIVE FUNCTION

❖ Los Angeles airport study

Cohen S. *Am Psychol.*, 1980, 35:231-43.

❖ New York airport city

Evans G. *Environment and Behavior*, 1997, 29(5):638-656.

❖ Munich airport study

Evans G. *Psychological Science*, 1998, 9:75-77; *Psychological Science*, 1995, 6:333-38

❖ Heathrow studies

Haines MM. *Psychological Medicine*, 2001a,b,c; *J Epidemiol Community Health*, 2002, 56(2):139

Over 20 studies have reported that noise **adversely affects** children's academic performance

33

Many studies have reported that noise can adversely affect children's academic performance. Transport noise is well-studied. Some of the most important studies are the Los Angeles airport study, the New York airport study, the Munich and Heathrow studies.

- AIM: To assess noise exposure in school children in urban center in different residential areas and to examine psychosocial effects of chronic noise exposure in school children, taking into account their socioeconomic status. METHODS: We measured community noise on specific measurement points in residential-administrative-market area and suburban residential area. We determined the average energy-equivalent sound level for 8 hours (LAeq, 8 h) or 16 hours (LAeq, 16 h) and compared measured noise levels with World Health Organization (WHO) guidelines. Psychological effects were examined in two groups of children: children exposed to noise level LAeq, 8 h >55 dBA (n=266) and children exposed to noise level LAeq, 8 h <55 dBA (n=263). The examinees were schoolchildren of 10-11 years of age. We used a self-reported questionnaire for each child - Anxiety test (General Anxiety Scale) and Attention Deficit Disorder Questionnaire intended for teachers to rate children's behavior. We used Mann Whitney U test and multiple regression for identifying the significance of differences between the two study groups. RESULTS: School children who lived and studied in the residential-administrative-market area were exposed to noise levels above WHO guidelines (55 dBA), and school children who lived and studied in the suburban residential area were exposed to noise levels below WHO guidelines. Children exposed to LAeq, 8 h >55 dBA had significantly decreased attention (Z=-2.16; p=0.031), decreased social adaptability (Z =-2.16; p=0.029), and increased opposing behavior in their relations to other people (Z=-3; p=0.001). We did not find any correlation between socioeconomic characteristics and development of psychosocial effects. CONCLUSION: School children exposed to elevated noise level had significantly decreased attention, and social adaptability, and increased opposing behavior in comparison with school children who were not exposed to elevated noise levels. Chronic noise exposure is associated with psychosocial effects in school children and should be taken as an important factor in assessing the psychological welfare of the children.*

MUNICH AIRPORT SCHOOL PERFORMANCE

- ❖ Closure of old airport, opening of new airport
- ❖ Deficits in long-term memory and reading around old airport
- ❖ Impairments diminish within 2 years after airport closed
- ❖ Same impairments develop in new group of children within 2 years of new airport opening

US Transportation Security Administration

Hygge S. *Psychol Sci.* (2002)13(5):469

34

When an old airport was closed down in Munich, deficits in long term memory and reading in children exposed to the old airport improved within 2 years of the airport's closure and the associated decreased noise exposure. Interestingly, the children exposed to noise from the new airport replacing the old began to have the same deficits in long term memory and reading that were seen in the children exposed to the old airport—also within 2 years.

Reference:

•Hygge S. et al. A prospective study of some effects of aircraft noise on cognitive performance in schoolchildren, *Psychol Sci.*, 2002, 13(5):469.

Before the opening of the new Munich International Airport and the termination of the old airport, children near both sites were recruited into aircraft-noise groups (aircraft noise at present or pending) and control groups with no aircraft noise (closely matched for socioeconomic status). A total of 326 children (mean age = 10.4 years) took part in three data-collection waves, one before and two after the switch-over of the airports. After the switch, long-term memory and reading were impaired in the noise group at the new airport, and improved in the formerly noise-exposed group at the old airport. Short-term memory also improved in the latter group after the old airport was closed. At the new airport, speech perception was impaired in the newly noise-exposed group. Mediation analyses suggest that poorer reading was not mediated by speech perception, and that impaired recall was in part mediated by reading.

STRENGTH OF EVIDENCE FOR EFFECTS OF AIRCRAFT NOISE ON CHILDREN

HEALTH OUTCOME	STRENGTH OF EVIDENCE
Annoyance	Sufficient
Hearing loss	Sufficient
Cognitive performance - reading	Sufficient
Cognitive performance - memory	Sufficient
Cognitive performance - auditory discrimination	Sufficient
Cognitive performance - speech perception	Sufficient
Cognitive performance - academic performance	Sufficient
Cognitive performance - attention	Inconclusive
Motivation	Sufficient / limited
Wellbeing/perceived stress	Sufficient / limited
Catecholamine secretion	Limited / inconclusive
Hypertension	Limited (weak associations)
Psychiatric disorder	Inconclusive / no effect
Sleep disturbance	Inadequate / no effect
Birth weight	Inadequate
Immune effects	Inadequate

Here is a brief summary slide examining the weight of the evidence for health outcomes in children from aircraft noise. We are indebted to Dr. Stephen Stansfeld (Queen Mary, University of London) for kindly lending us this and many of the previous slides for this project. This slide highlights the clear associations in children between annoyance, hearing loss and impaired cognitive performance and excess noise. The lower categories are still in need of investigation.

6. Discussion

EFFECTS OF NOISE BY AGE-GROUP

- ❖ **Fetus**
- ❖ **Infant**
- ❖ **Pre-school, school-aged children**
- ❖ **Teenager**
- ❖ **Youth**

EFFECTS OF NOISE ON THE FETUS

- ❖ Growth retardation
 - Occupational exposure of the mother to noise
 - Environmental noise unlikely to cause effects, but exposure to chronic low-dose noise requires more study

- ❖ Hearing impairment
 - Possible effects

There are several paediatric populations which may be at increased risk of harm from noise. The fetus is one in which there is some evidence that occupational exposure to a pregnant woman may result in growth retardation and/or hearing impairment. Little is known about the effects of non-occupational noise on fetal development, and further studies are needed.

EFFECTS OF NOISE ON INFANTS

Pre-term and full-term baby

- ❖ Exposed to "Neonatal Intensive Care Unit" (NICU) noise
 - Pre-term babies have immature hearing organs / systems

- ❖ Adverse noise-induced effects on the pre-term baby
 - **Hearing impairment:** possible effect
 - **Sleep disturbances:** awakening, sleep disruption
 - **Others:** crying

Babies who are born pre-term or require intensive care in hospital are exposed to large amounts of noise from incubators and busy hospital settings. Furthermore, this noise may be continuous, 24 hours/day.

They are exposed to "Neonatal Intensive Care Unit" (NICU) noise (60 - 90 dBA max. 120 dBA) and noise inside the incubators (60 – 75 dBA max. 100 dBA). Pre-term babies must cope with their environment with immature organ systems (auditory, visual and central nervous system). These last stages of maturation occur, in part, during the time the pre-term child is in an incubator or neonatal intensive care unit (NICU).

References:

- Brandon DH. Effect of Environmental Changes on Noise in the NICU. *Advances in Neonatal Care*, 2008, 8(5):S5-S10
- Milette IH, Carnevale FA. I'm trying to heal...noise levels in a pediatric intensive care unit. *Dynamics*, 2003, 14:14-21.

The literature demonstrates clearly that most intensive care units exceed the standard recommendations for noise levels in hospitals, and that high noise levels have negative impacts on patients and staff. The purpose of this study was to evaluate the level of noise in a PICU and compare it to the recommendations of international bodies. We outline recommendations to promote the awareness of this problem and suggest strategies to decrease the level of noise in a PICU. The orientations of these strategies are threefold: 1) architectural-acoustic design, 2) equipment design and, most importantly, 3) staff education.

Children and noise

EFFECTS OF NOISE IN PRE-SCHOOL AND SCHOOL-AGED CHILDREN

- ❖ Hearing impairment
 - In isolated cases by toys or equipment
- ❖ Sleep disturbances
 - Earlier responses than adults (EEG awakenings)
- ❖ Somatic effects
 - Blood pressure and stress hormones
- ❖ Psycho-social effects
 - No studies on behaviour with high environmental noise levels
 - Cognitive tasks are impaired, like reading, long term memory, attention and motivation
- ❖ Vocal nodule

40

EEG: electroencephalogram

<<READ SLIDE>>

Children raise their voices and risk developing hoarseness and vocal nodules because of noise and relative overcrowding. The number of children screaming so much and so loudly that their voices are damaged and require treatment increased in Denmark during the 1990s. Noise in schools and day care institutions results in boys' voices getting hoarse and girls' voices squeaky. Children with vocal nodules can be difficult to understand and risk losing their voices altogether. Other children become so tired of screaming or of trying to make themselves heard that they give up saying anything at all and, for example, do not raise their hands in class. If children give up speaking, their voices do not develop properly and language learning is not reinforced.

•Clark C et al. Exposure-effect relations between aircraft and road traffic noise exposure at school and reading comprehension: the RANCH project. *Am J Epidemiol*. 2006, 163:27-37.

Transport noise is an increasingly prominent feature of the urban environment, making noise pollution an important environmental public health issue. This paper reports on the 2001-2003 RANCH project, the first cross-national epidemiologic study known to examine exposure-effect relations between aircraft and road traffic noise exposure and reading comprehension. Participants were 2,010 children aged 9-10 years from 89 schools around Amsterdam Schiphol, Madrid Barajas, and London Heathrow airports. Data from The Netherlands, Spain, and the United Kingdom were pooled and analyzed using multilevel modeling. Aircraft noise exposure at school was linearly associated with impaired reading comprehension; the association was maintained after adjustment for socioeconomic variables (beta = -0.008, p = 0.012), aircraft noise annoyance, and other cognitive abilities (episodic memory, working memory, and sustained attention). Aircraft noise exposure at home was highly correlated with aircraft noise exposure at school and demonstrated a similar linear association with impaired reading comprehension. Road traffic noise exposure at school was not associated with reading comprehension in either the absence or the presence of aircraft noise (beta = 0.003, p = 0.509; beta = 0.002, p = 0.540, respectively). Findings were consistent across the three countries, which varied with respect to a range of socioeconomic and environmental variables, thus offering robust evidence of a direct exposure-effect relation between aircraft noise and reading comprehension.

Children and noise

EFFECTS OF NOISE.... A WORD APART FOR **TEENAGERS!!**

- ❖ Potential sources of hearing impairment
 - Noisy toys, firecrackers, boom-cars, musical instruments, others
- ❖ Discotheques and pop concerts
 - Exposure similar to occupational exposures
 - Use of music headphones
- ❖ Loss of hearing may go undetected for many years after chronic exposure to high levels of noise
- ❖ Increased rates of adolescent hearing impairment in last 3 decades
- ❖ Protection needed from the start
 - Be instructed to use personal hearing protection
 - Not only at work but also at technical and polytechnic schools

41

<<READ SLIDE>>

Noise is associated with youth. Often, teenagers' exposure is constant. Prolonged exposure can lead to a transitory loss of 10-30 dB for several minutes after the noise ceases. Frequency of exposure, personal variability, and age of exposure determine the pattern of the damage.

Music occurs outside of the major frequencies of the human voice and over exposure to loud music causes loss of discrimination at low frequencies which may not be detected without formal testing for years. "Walkman" equipment is designed for emissions not higher than 80 dB, but the combination of an immature hearing system and a prolonged use may cause cumulative damage. Technology can be modified to bypass factory-imposed limitations and result in very loud music/noise exposure. Loss of concentration because of the focus on the music, in the presence of a potentially dangerous situation, makes a young person more vulnerable to accidents.

Teenagers should be instructed to use personal hearing protection as soon as they start being exposed to high noise levels, not only at work, but also at technical and polytechnic schools. If noise-abatement measures are not taken, good hearing will not be preserved and noise-induced tinnitus will not be prevented. The extent of hearing impairment in teenagers, caused by occupational noise exposure, and exposure at technical and polytechnic schools is unknown.

There are insufficient numbers of studies on somatic, psycho-social and behavioural effects of noise in teenagers.

Children and noise

PREVENTION AND INTERVENTION

- ❖ More research needed, especially in vulnerable groups
- ❖ Preventive action
 - Noise has to be controlled at the source
 - Hearing protection devices are a last resort
- ❖ Child hearing conservation programs
- ❖ Education and dissemination

43

Future research:

- Effects of noise on cognitive functions.
- Effects of noise on children's sleep.
- Magnitude/significance of noise annoyance.
- Children's perception and risk perception.
- Settings: home, schools, hospital, day care centres.
- Teenagers' attention when driving and listening to loud music.
- Effect of non-audible noise.
- Identification of more vulnerable groups!
- Intervention programs/best practices for preventing harmful effects.

Preventive actions

Noise has to be controlled at the source by:

- Reducing.
- Enclosing the vibrating surfaces.
- Placing sound absorbers and other protections.

Hearing protection devices are a last resort!

Child hearing conservation program

- Noise monitoring where children live, study and play.
- Hearing protection programs diffusion for teachers and parents.
- Vibration detection and protection.
- Protection of the pregnant woman.

Education and dissemination

References:

- Folmer RL, et al. Hearing conservation education programs for children: a review. *J Sch Health*. 2002;72:51-7.
- Prevalence of noise-induced hearing loss (NIHL) among children is increasing. Experts have recommended implementation of hearing conservation education programs in schools. Despite these recommendations made over the past three decades, basic hearing conservation information that could prevent countless cases of NIHL remains absent from most school curricula. This paper reviews existing hearing conservation education programs and materials designed for children or that could be adapted for classroom use. This information will be useful as a resource for educators and school administrators and should encourage further development, implementation, and dissemination of hearing conservation curricula. The overall, and admittedly ambitious, goal of this review is to facilitate implementation of hearing conservation curricula into all US schools on a continuing basis. Ultimately, implementation of such programs should reduce the prevalence of noise-induced hearing loss among children and adults.*
- Moeller. Environmental Health, *Harvard University Press*, 1992.

WHERE TO INTERVENE?

❖ Techniques for reducing or eliminating noise

- At the source
- By installing a barrier between the source and the recipient
- At the point of reception / At the human recipient

❖ Potential settings for intervention

- NICU
- Child care settings
- Primary schools
- Discotheques and rock festivals

❖ Address external and internal noise sources

<<READ SLIDE>>

Identified potential settings for intervention

1. NICU

2. Child care settings : more and more children stay in various child care settings. These play an important role in the initial stages of children beginning to establish their basic education.

3. Primary schools : primary school children often spend long periods of time in one classroom, and a noisy room can adversely affect the occupants of that room.

4. Discotheques and rock festivals : the noise level can be very high in discotheques, often resulting in tinnitus or a temporary threshold shift among patrons. Many major cities have festivals, and many of the noisier attractions inevitably appeal to younger people.

• Byers JF, et al. Sound level exposure of high-risk infants in different environmental conditions. *Neonatal Netw.* 2006, 25(1):25-32.

PURPOSES: To provide descriptive information about the sound levels to which high-risk infants are exposed in various actual environmental conditions in the NICU, including the impact of physical renovation on sound levels, and to assess the contributions of various types of equipment, alarms, and activities to sound levels in simulated conditions in the NICU. DESIGN: Descriptive and comparative design. SAMPLE: Convenience sample of 134 infants at a southeastern quaternary children's hospital. MAIN OUTCOME VARIABLE: A-weighted decibel (dBA) sound levels under various actual and simulated environmental conditions. RESULTS: The renovated NICU was, on average, 4-6 dBA quieter across all environmental conditions than a comparable nonrenovated room, representing a significant sound level reduction. Sound levels remained above consensus recommendations despite physical redesign and staff training. Respiratory therapy equipment, alarms, staff talking, and infant fussiness contributed to higher sound levels. CONCLUSION: Evidence-based sound-reducing strategies are proposed. Findings were used to plan environment management as part of a developmental, family-centered care, performance improvement program and in new NICU planning.

HOW TO INTERVENE?

Technically

- ❖ Planning and designing outdoors and indoors “soundscapes”
- ❖ Improving road surfaces and developing green spaces and green barriers
- ❖ Developing noise barriers, building sound insulation
- ❖ Planning internal spaces according to activities (e.g. schools, sports-centres, others that involve noise), strategically using the space & location
- ❖ Reducing internal noise (eg. fans, ventilators)
- ❖ Using sound-absorbent materials
- ❖ Setting sound limits for concerts
- ❖ Increasing public and professional education to recognize noise pollution and reduction!

<<READ SLIDE>>

HOW TO INTERVENE?

Organizationally and Educationally

- ❖ Educating children, adults, professionals
- ❖ Teaching methods/interventions
- ❖ Disseminating information
- ❖ Informing the media and decision-makers and health professionals!
- ❖ Creating silent areas (“silence islands”) for resting
- ❖ Distributing earplugs at work and setting limits for the earphones
- ❖ Identifying and turning off noise at the source!

<<READ SLIDE>>

HOW TO INTERVENE?

Planning

- ❖ **Identifying noise sources and recognizing noise as a problem**
- ❖ **Recognizing health effects in children caused by noise**
- ❖ **Recognizing and diagnosing adults' health problems originated in childhood exposure**
- ❖ Raising awareness
- ❖ Setting-up noise control campaigns in hospitals and schools
- ❖ Applying the “Precautionary Principle”
- ❖ Thinking about noise exposure when planning the settings where children dwell
- ❖ Promoting sound landscape design
- ❖ Developing noise mapping, action plans, community involvement
- ❖ Standardizing noise measurements

POINTS FOR DISCUSSION

<<NOTE TO USER: Add points for discussion according to the needs of your audience.>>

Children and noise

ACKNOWLEDGEMENTS

WHO is grateful to the US EPA Office of Children's Health Protection for the financial support that made this project possible and for the data, graphics and text used in preparing these materials.

First draft prepared by Lilian Corra, MD, Argentina

With the advice of the Working Group on Training Package for the Health Sector:
Cristina Alonzo, MD (Uruguay); Yona Amitai, MD, MPH (Israel); Stephan Boese-O'Reilly, MD, MPH (Germany); Stephania Borgo MD (ISDE, Italy); Irena Buka, MD (Canada); Ligia Fruchtengarten, MD (Brazil); Amalia Laborde, MD (Uruguay); Leda Nemer, TO (WHO/EURO); R. Romizzi, MD (ISDE, Italy); Katherine M. Shea, MD, MPH (USA) .

Reviewers: Yoon JungWon (Republic of Korea)

WHO CEH Training Project Coordination: Jenny Pronczuk, MD
Medical Consultant: Ruth A. Etzel, MD, PhD
Technical Assistance: Marie-Noel Bruné, MSc

Latest update: December 2009 (C. Espina, PhD)

We are indebted to Dr. Stephen Stansfeld (Queen Mary, University of London) for kindly lending us slides for this project.

Children and noise

DISCLAIMER

- The designations employed and the presentation of the material in this publication do not imply the expression of any opinion whatsoever on the part of the World Health Organization concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted lines on maps represent approximate border lines for which there may not yet be full agreement.
- The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by the World Health Organization in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.
- The opinions and conclusions expressed do not necessarily represent the official position of the World Health Organization.
- This publication is being distributed without warranty of any kind, either express or implied. In no event shall the World Health Organization be liable for damages, including any general, special, incidental, or consequential damages, arising out of the use of this publication
- The contents of this training module are based upon references available in the published literature as of June 2004. Users are encouraged to search standard medical databases for updates in the science for issues of particular interest or sensitivity in their regions and areas of specific concern.
- If users of this training module should find it necessary to make any modifications (abridgement, addition or deletion) to the presentation, the adaptor shall be responsible for all modifications made. The World Health Organization disclaims all responsibility for adaptations made by others. All modifications shall be clearly distinguished from the original WHO material.
